

How Middleware Works in ASP.NET Core

What is Middleware?

Middleware is a software component in ASP.NET Core that processes HTTP requests and responses. Every request passes through a pipeline of middleware components before reaching the controller.

Middleware Flow

Client Request
↓
UseCors
↓
UseStaticFiles
↓
UseHttpsRedirection
↓
UseAuthorization
↓
Controller
↓
Response

Example Middleware Pipeline

```
app.UseCors('CorsPolicy');  
app.UseStaticFiles();  
app.UseHttpsRedirection();  
app.UseAuthorization();
```

Summary

Middleware acts as a request-processing pipeline. A request travels through each middleware component in order, and only after all checks pass does it reach the controller.
